

MRI Right Shoulder · Synthetic Demo Report

Educational sample only · synthetic demo, not a real patient report.

EXAM:

MRI of the right shoulder without contrast.

CLINICAL HISTORY:

45-year-old with shoulder pain after overhead activity. Evaluate rotator cuff.

TECHNIQUE:

Multiplanar T1- and T2-weighted sequences of the right shoulder were obtained.

COMPARISON:

None available.

FINDINGS:

A near-complete tear of the supraspinatus tendon is present at the footprint, with residual thin fibers. Fluid surrounds the remaining tendon. Mild AC joint degenerative changes are noted. The long head of the biceps tendon is intact. No full-thickness infraspinatus or subscapularis tear is identified.

IMPRESSION:

1. Near-complete tear of the right supraspinatus tendon.
2. Fluid signal surrounding the residual tendon fibers.
3. Mild acromioclavicular joint degenerative changes.

RECOMMENDATIONS:

Clinical correlation. Orthopedic follow-up as clinically indicated.
